Flying probe - Wikipedia

In-circuit test is an example of white box testing where an electrical probe tests a populated printed circuit board, checking for shorts, opens, resistance, capacitance, and other basic quantities which will show whether the assembly was correctly fabricated. It may be performed with a bed of nails type test fixture and specialist test equipment, or with a fixtureless in-circuit test setup.

In-circuit test - Wikipedia

The fixtureless in-circuit test (FICT), also known as the flying probe test, is a type of ICT that operates without the custom fixtures, reducing the overall cost of the test. First introduced in 1986 , FICT uses a simple fixture to hold the board while test pins move around and test relevant points on it using a software-controlled

Turn on the ESR meter, and short its leads until you get 0 reading on its screen. If the screen is already showing 0 reading, then there is no need to short the leads. Place the red lead of ESR meter to a positive and black lead to the negative terminal of the capacitor under test. Note the readings on ESR meter.
