Linear programming is basically a fancy term for a constrained optimization problem consisting of linear constraints and a linear objective function. In this word problem, we formulate a set of constraints and an objective function, graph the feasible region, identify corner points, and finally plug those points into the objective to find the maximum profit.

Linear programming can be used to solve financial problems involving multiple limiting factors and multiple alternatives. However, where the number of alternatives (e.g. types of products) is greater than 2, only a specific method of linear programming (known as the simplex method) can be used to determine the optimum solution.

A linear programming problem with an unbounded set may or may not have an optimal solution, but if there is an optimal solution, it occurs at a corner point. A bounded set is a set that has a boundary around the feasible set. A linear programming problem with a bounded set always has an optimal solution.

Linear Programming problems are typically word problems - not cool. But most will fit in the same mold: for these beginning problems, they will have two types of unknowns or variables, like earrings and necklaces, and they will involve inequalities. You'll just put the first variable on the x -axis and the second on the y -axis.
